

## 19V Vin Quad Channel Power Management IC

### FEATURES

- x Wide Input Voltage Range: 4V-19V
- x Synchronous HV Pre-Buck1:
  - Up to 1.2A Continuous Output Current
  - Auto-adaptive Output Voltage Depends on LDO Output Voltage
- x Synchronous LV Post-Buck2:
  - Powered by Pre-Buck1
  - Up to 0.6A Continuous Output Current
  - Fixed Output Voltage of 1.8V
- x Synchronous LV Post-Buck3:
  - Powered by Pre-Buck1
  - Up to 1.2A Continuous Output Current
  - Adjustable Output Voltage: 1.1V/1.2V/1.3V/1.5V
- x LV Post-LDO:
  - Powered by Pre-Buck1
  - Up to 0.3A Continuous Output Current
  - Adjustable Output Voltage: 2.7V/2.8V/2.9V/3.3V
  - Low Noise and High PSRR
- x Low Shutdown Current: 1uA
- x Fixed 2.2MHz Switching Frequency
- x Integrated Frequency Dither for EMI Mitigation
- x FCCM Operation
- x 60ns Minimum On-time
- x 6 Flexible Sequence via External Resistor
- x 9 Flexible Output Voltage via External Resistor
- x Push-pull Power Good Indicator
- x Integrated Hiccup Mode Protection Features:
  - Input Over-voltage Protection
  - Output Over-voltage Protection
  - Output Under-voltage Protection
  - Over-current Protection
  - Adjustable Under-voltage Lockout
  - Thermal Shutdown Protection
- x Available in QFN-18L(2.5mm\*3.5mm)

### APPLICATIONS

- x Compact Camera Module
- x Multi-channel Power Solution

### DESCRIPTION

The SCT61240 is a highly integrated power management IC (PMIC) optimized for camera system. It integrates three high efficiency synchronous BUCK converters (HVBUCK1, LVBUCK2, LVBUCK3), and a high-PSRR low noise LDO with OV/UV monitoring on all outputs.

VOUT1 is the output of BUCK1, which is powered from VIN (Power Over Coax) and can output 1.2A continuous current with the output voltage set to LDOOUT+300mV/500mV or fixed 3.3V.

VOUT2 is the output of BUCK2, which is powered from VOUT1 and can output 600mA continuous current with the output voltage fixed to 1.8V.

VOUT3 is the output of BUCK3, which is powered from VOUT1 and can output 1.2A continuous current with the output voltage set to 1.1V/1.2V/1.3V/1.5V through RSET PIN for different sensors.

LDOOUT is the output of LDO, which is powered from VOUT1 (need to connect LDOIN to VOUT1) and can output 300mA continuous current with the output voltage set to 2.7V/2.8V/2.9V/3.3V through RSET PIN for different sensors.

With a compact QFN2.5x3.5 package, the SCT61240 greatly reduces external components count and PCB space.

### TYPICAL APPLICATION

## REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version

Revision 1.0: Released to Market

Revision 1.1: Update DEVICE ORDER INFORMATION

Revision 1.2: Corrected few typographical errors.

Revision 1.3: Update DEVICE ORDER INFORMATION.

## PIN CONFIGURATION

Top View: 18-Lead FCTQFN 2.5mmx3.5mm

- (1) Stresses beyond those listed under Absolute Maximum Rating may cause device permanent damage. The device is not guaranteed to function outside of its Recommended Operation Conditions.
- (2) The IC includes over temperature protection to protect the device during overload conditions. Junction temperature will exceed 170°C when over temperature protection is active. Continuous operation above the specified maximum operating junction temperature will reduce lifetime.

## PIN FUNCTIONS

| NAME  | NO. | DESCRIPTION                                                                                                                                                                                                            |
|-------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PGND2 | 1   | Power ground for Buck 2 and Buck 3. Should be electrically connected to the system power ground plane with the shortest and lowest-impedance connection possible.                                                      |
| VOUT1 | 2   | Feedback for Buck 1 and power source for Buck 2 and Buck 3. Connect VOUT1 pin to the buck 1 output directly. A decoupling capacitor to ground is recommended to be placed close to VOUT1 to minimize switching spikes. |
| SW1   | 3   | Buck 1 switch node. SW is the output of the internal power switch. Connect to an external inductor using a wide PCB trace.                                                                                             |

# SCT61240

## THERMAL INFORMATION(continued)

| PARAMETER             | THERMAL METRIC                                           | QFN-18L | UNIT |
|-----------------------|----------------------------------------------------------|---------|------|
| $R_{\theta JC (top)}$ | Junction to case (top) thermal resistance <sup>(1)</sup> | 46.8    | °C/W |
| $R_{\theta JB}$       | Junction to board thermal resistance <sup>(1)</sup>      | 8.8     |      |

(1) SCT provides  $R_{\theta JA}$  and  $R_{\theta JC}$  numbers only as reference to estimate junction temperatures of the devices.  $R_{\theta JA}$  and  $R_{\theta JC}$  are not a characteristic of package itself, but of many other system level characteristics such as the design and layout of the printed circuit board (PCB) on which the SCT61240 is mounted, thermal pad size, and external environmental factors. The PCB board is a heat sink that is soldered to the leads and thermal pad of the SCT61240. Changing the design or configuration of the PCB board changes the efficiency of the heat sink and therefore the actual  $R_{\theta JA}$  and  $R_{\theta JC}$ .

## OPERATION

### Overview

The SCT61240 is a highly integrated power management IC (PMIC) optimized for camera system. It integrates three high efficiency synchronous BUCK converters (HVBUCK1, LVBUCK2, LVBUCK3), and a high-PSRR low noise LDO with OV/UV monitoring on all outputs.

VOUT1 is the output of BUCK1, which is powered from VIN (Power Over Coax) and can output 1.2A continuous current with the output voltage set to LDOOUT+300mV/500mV or fixed 3.3V.

VOUT2 is the output of BUCK2, which is powered from VOUT1 and can output 600mA continuous current with the output voltage fixed to 1.8V.

VOUT3 is the output of BUCK3, which is powered from VOUT1 and can output 1.2A continuous current with the output voltage set to 1.1V/1.2V/1.3V/1.5V through RSET PIN for different sensors.

LDOOUT is the output of LDO, which is powered from VOUT1 (need to connect LDOIN to VOUT1) and can output 300mA continuous current with the output voltage set to 2.7V/2.8V/2.9V/3.3V through RSET PIN for different sensors.

With a compact QFN2.5x3.5 package, the SCT61240 greatly reduces external components count and PCB space.

### VIN and EN UVLO

When the VIN pin voltage rises above 3.8V and the EN pin voltage exceeds the enable threshold of 1.2V, the device is enabled. And the device disables when the VIN pin voltage falls below 3.8V or when the EN pin voltage is below 1.1V.

An internal 10MΩ resistor pulls EN pin to an internal 5V power supply allows the device to be enabled when EN pin is floating to simplify the system design.

### High Efficiency Buck Converters

All the 3 BUCKs employ 2.2MHz fixed frequency peak current mode control with forced continuous conduction mode (FCCM). Built-in UVLO, soft-start (0.4ms/0.8ms/1.2ms/1.6ms options by OTP trim), compensation and hiccup (or latch off option by OTP trim) make the buck converters easily to be used by minimizing the off-chip component count.

For buck1, an external 100nF ceramic bootstrap capacitor between BST and SW1 pin powers high-side power MOSFET gate driver. The bootstrap capacitor voltage is charged from an integrated voltage regulator when high-side power MOSFET is off and low-side power MOSFET is on.

The converters have proprietary designed gate driver scheme to resist switching node ringing without sacrificing MOSFET turn-on and turn-off time, which further erases high frequency radiation EMI noise caused by the MOSFETs hard switching.

The converters implement over current protection with cycle-by-cycle limiting high-side MOSFET peak current and also low-side MOSFET valley current to avoid inductor current running away during unexpected overload and hiccup

## Under Voltage Protection

If an output falls below the under voltage protection threshold, all outputs will shut off for the hiccup time. When hiccup ends, the normal power up sequence will start again according to the SEQ and RSET setting. When entry hiccup, the output discharge will operate during the hiccup time.

## Over Current Protection (OCP)

For the three bucks and LDO, the SCT61240 provides both peak and valley current limit designed to limit the peak/valley inductor current to ensure that the switching currents remain within the device capabilities during overload conditions or during an output short circuit.

When the HS-FET turns on, the chip monitors the increased IL through the relevant operating main power switch. Once the peak IL exceeds the peak current limit threshold, the HS-FET turns off immediately, and the LS-FET turns on to conduct and decrease IL. The HS-FET does not turn on again until IL falls below the valley current limit threshold.

## Power Good

The PG pin is a push-pull output. It goes to logic high when the device is powered on, and all outputs are within the power good range, and no faults reported. The high output level can be programmed to either 3.3V or 1.8V.

PG will assert low when any of below events occur:

- xBuck1's output is out of power good range or VOUT OV/UV range

- xBuck2's output is out of power good range or VOUT OV/UV range

- xBuck3's output is out of power good range or VOUT OV/UV range

- xDLDO's output is out of power good range or VOUT OV/UV range

- xJunction temperature is over Thermal Shutdown point

- xVIN is higher than VIN OVP threshold

## Hiccup or Latch off Protection

When below faults are detected, the SCT61240 will enter hiccup or latch off mode (programmable option). When select hiccup mode and entry hiccup, all the channels shut off for 3.6ms, and then the normal power up sequence will start again according to the SEQ and RSET setting. When select latch off mode and entry latch off, all the channels shut off and not restart unless VIN/EN power on reset (POR).

The faults that make the device entry hiccup/latch off protection:

- xBuck1's output is out of VOUT OV/UV range

- xBuck2's output is out of VOUT OV/UV range

- xBuck3's output is out of VOUT OV/UV range

- xDLDO's output is out of VOUT OV/UV range

- xJunction temperature is over Thermal Shutdown point

- xVIN is higher than VIN OVP threshold

## Output Discharge

In order to discharge the energy of output capacitor during power off sequence, all channels have active discharge path from their output to ground. The discharge path is turn-on when channel is disabled.

## Internal Soft- Start

The soft start function is implemented to prevent the PMIC output voltage from overshooting during start-up. When the PMIC starts up, the internal circuitry of each power rail generates a soft-start voltage that ramps up from 0V. The soft-start period lasts until the voltage on the soft-start capacitor exceeds the reference voltage. At this point, the reference voltage takes over.

### Frequency Spread Spectrum

To meet CISPR and EMI compliances, the SCT61240 implements Frequency Spread Spectrum (FSS) function. The FSS circuitry shifts the 2.2MHz switching frequency within  $\pm 5\%$  range and  $1/512$  of the switching frequency periodically. Therefore, the SCT61240 can guarantee that the switching frequency does not drop into the 1.8MHz AM band limit.

### Thermal Shutdown

The SCT61240 protects the device from damage during excessive heat and power dissipation condition. Once the junction temperature exceeds 170C, the thermal sensing circuit disable all channels and enter hiccup or latch off. When the junction temperature falls below 150C and hiccup ends, then the device restarts.

### Power on/off Sequence Control

For power on, the SCT61240 supports 6 power-on sequences for buck2&3 and LDO through SEQ pin. Since the output of BUCK1 is the power for the next three channels, BUCK1 is always set to startup first.

For power off, through VIN/EN or entry hiccup/latch off, all channels power off simultaneously.

Connect a resistor between SEQ and GND to set the power on sequence before enabling the device. The SEQ detection only activated at the beginning of power on, and the sequence configuration is latched once SEQ detection done. When the resistance selected out of range, CH2&CH3&CH4 are disabled. Any change during the power on procedure is not guarantee to the correct power-on sequence.

Below table shows the power-on sequence with its corresponding resistance. CH1 is BUCK1, CH2 is BUCK2, CH3 is BUCK3, CH4 is LDO.

Table 1. Power-On Sequence Control

## Output Voltage Setting

The device provides 9 flexible voltage setting through RSET PIN for various sensors. Connect a resistor between RSET and GND to set the output voltage of each channel before enabling the device. The RSET detection only activated at the beginning of power on, and the output voltage configuration is latched once RSET detection done. Any change during the power on procedure is not guarantee to the correct output voltage setting.

Below table shows the output voltage setting with its corresponding resistance.

## APPLICATION INFORMATION

## Typical Application

## Under Voltage Lock -Out

An external voltage divider network of  $R_1$  from the input to EN pin and  $R_2$  from EN pin to the ground can set a higher input voltage's Under Voltage Lock-Out (UVLO) threshold. The UVLO has two thresholds, one for power up when the input voltage is rising and the other for power down or brown outs when the input voltage is falling. Use Equation 1 and Equation 2 to calculate the values of  $R_1$  and  $R_2$  resistors.

$$V_{IN} \geq V_{rise} \left( 1 + \frac{R_1}{R_2} \right) \quad (1)$$

$$V_{IN} \leq V_{fall} \left( 1 + \frac{R_1}{R_2} \right) \quad (2)$$

where

- x  $V_{rise}$  is rising threshold of  $V_{IN}$  UVLO
- x  $V_{fall}$  is falling threshold of  $V_{IN}$  UVLO
- x  $V_{ENrise}$  is rising threshold of EN UVLO
- x  $V_{ENfall}$  is falling threshold of EN UVLO

Figure 14. System UVLO by enable divide

## Inductor Selection

There are several factors should be considered in selecting inductor such as inductance, saturation current, the RMS current and DC resistance(DCR). Larger inductance results in less inductor current ripple and therefore leads to lower output voltage ripple. However, the larger value inductor always corresponds to a bigger physical size, higher series resistance, and lower saturation current. A good rule for determining the inductance to use is to allow the inductor peak-to-peak ripple current to be approximately 20%~40% of the maximum output current.

The peak-to-peak ripple current in the inductor  $I_{LPP}$  can be calculated as in Equation 3.

$$I_{LPP} = \frac{V_{IN} - V_{OUT}}{L \cdot f_{sw}} \quad (3)$$

Where

- x  $I_{LPP}$  is the inductor peak-to-peak current
- x  $L$  is the inductance of inductor
- x  $f_{sw}$  is the switching frequency
- x  $V_{OUT}$  is the output voltage
- x  $V_{IN}$  is the input voltage

Since the inductor-current ripple increases with the input voltage, so the maximum input voltage in application is always used to calculate the minimum inductance required. Use Equation 4 to calculate the inductance value.

$$L_{MIN} = \frac{V_{IN} - V_{OUT}}{f_{sw} \cdot I_{LPP}} \quad (4)$$

Where

- x  $L_{MIN}$  is the minimum inductance required
- x  $f_{sw}$  is the switching frequency
- x  $V_{OUT}$  is the output voltage

- x  $V_{IN(max)}$  is the maximum input voltage
- x  $I_{OUT(max)}$  is the maximum DC load current
- x LIR is coefficient of  $I_{LPP}$  to  $I_{OUT}$

The total current flowing through the inductor is the inductor ripple current plus the output current. When selecting an inductor, choose its rated current especially the saturation current larger than its peak operation current and RMS current also not be exceeded. Therefore, the peak switching current of inductor,  $I_{LPEAK}$  and  $I_{LRMS}$  can be calculated as in equation 5 and equation 6.

$$I_{LPEAK} = I_{OUT} + \frac{\Delta I_L}{2} \quad (5)$$

$$I_{LRMS} = \sqrt{I_{OUT}^2 + \frac{5}{24} \Delta I_L^2} \quad (6)$$

Where

- x  $I_{LPEAK}$  is the inductor peak current
- x  $I_{OUT}$  is the DC load current
- x  $I_{LPP}$  is the inductor peak-to-peak current
- x  $I_{LRMS}$  is the inductor RMS current

In overloading or load transient conditions, the inductor peak current can increase up to the switch current limit of the device. The most conservative approach is to choose an inductor with a saturation current rating greater than peak current limit. Because of the maximum  $I_{LPEAK}$  limited by device, the maximum output current that the SCT61240 can deliver also depends on the inductor current ripple. Thus, the maximum desired output current also affects the selection of inductance. The smaller inductor results in larger inductor current ripple leading to a lower maximum output current.

#### Input Capacitor Selection

The input current to the step-down DCDC converter is discontinuous, therefore it requires a capacitor to supply the AC current to the step-down DCDC converter while maintaining the DC input voltage. Use capacitors with low ESR for better performance. Ceramic capacitors with X5R or X7R dielectrics are usually suggested because of their low ESR and small temperature coefficients, and it is strongly recommended to use another lower value capacitor (e.g. 0.1uF) with small package size (0603) to filter high frequency switching noise. Place the small size capacitor as close to VIN and GND pins as possible.

The voltage rating of the input capacitor must be greater than the maximum input voltage. And the capacitor must also have a ripple current rating greater than the maximum input current ripple. The RMS current in the input capacitor can be calculated using Equation 7.

$$I_{GMRVQ} = I_{OUT} \sqrt{\frac{V_{SYX}}{V_{MR}} \left( 1 + \frac{V_{SYX}}{V_{MR}} \right)} \quad (7)$$

The worst case condition occurs at  $V_{IN}=2*V_{OUT}$ , where:

$$I_{GMRVQ} = 0.5 I_{SYX} \quad (8)$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

When selecting ceramic capacitors, it needs to consider the effective value of a capacitor decreasing as the DC bias voltage across a capacitor increasing.

The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using Equation 9 and the maximum input voltage ripple occurs at 50% duty cycle.

$$\Delta V_{MR} = \frac{I_{SYX}}{f_{WL}} \frac{V_{SYX}}{C_{MR}} \left( 1 - \frac{V_{SYX}}{V_{MR}} \right) \quad (9)$$

For this example, two 10μF, X7R ceramic capacitors rated for 50V in parallel are used. And a 0.1 μF for high-frequency filtering capacitor is placed as close as possible to the device pins.

#### Bootstrap Capacitor Selection

A 0.1μF ceramic capacitor must be connected between BOOT pin and SW pin for proper operation. A ceramic capacitor with X5R or better grade dielectric is recommended. The capacitor should have a 10V or higher voltage rating.

#### Output Capacitor Selection

The selection of output capacitor will affect output voltage ripple in steady state and load transient performance.

The output ripple is essentially composed of two parts. One is caused by the inductor current ripple going through the Equivalent Series Resistance ESR of the output capacitors and the other is caused by the inductor current ripple charging and discharging the output capacitors. To achieve small output voltage ripple, choose a low-ESR output capacitor like ceramic capacitor. For ceramic capacitors, the capacitance dominates the output ripple. For simplification, the output voltage ripple can be estimated by Equation 10 desired.

$$\Delta V_{SYX} = \frac{8_{EII} \cdot \bar{U} \cdot 8_{AC} \cdot F \cdot 8_{EII}}{8 \cdot \bar{U}_{PD}^6 \cdot \bar{U} \cdot \bar{U}_{EII} \cdot \bar{U}_{8AC}} \quad (10)$$

Where

- x  $\Delta V_{OUT}$  is the output voltage ripple
- x  $f_{SW}$  is the switching frequency
- x  $L$  is the inductance of inductor
- x  $C_{OUT}$  is the output capacitance
- x  $V_{OUT}$  is the output voltage
- x  $V_{IN}$  is the input voltage

Due to capacitor's degrading under DC bias, the bias voltage can significantly reduce capacitance. Ceramic capacitors can lose most of their capacitance at rated voltage. Therefore, leave margin on the voltage rating to ensure adequate effective capacitance. Typically, two 4.7μF ceramic output capacitors work for most applications. The LDO is specifically designed to work with a standard ceramic output capacitor to save space and improve performance. Larger output capacitors will improve load transient response and reduce noise at the cost of increased size. A 1μF to 20μF output capacitor should be placed to get stable output.

## Layout Guideline

Proper PCB layout is a critical for SCT61240's stable and efficient operation. The traces conducting fast switching currents or voltages are easy to interact with stray inductance and parasitic capacitance to generate noise and degrade performance. For better results, follow these guidelines as below:

1. Power grounding scheme is very critical because of carrying power, thermal, and glitch/bouncing noise associated with clock frequency. The thumb of rule is to make ground trace lowest impedance and power are distributed evenly on PCB. Sufficiently placing ground area will optimize thermal and not causing over heat area.
2. Place a low ESR ceramic capacitor as close to VIN pin and the ground as possible to reduce parasitic effect.
3. For operation at full rated load, the top side ground area must provide adequate heat dissipating area. Make sure top s.2 (n)-14 0 Td [0e1.1 (e)/BBi(pr).S.831 0 55.831 0 55(t)-JTJ 0.001 Tw -48.145 -1.-d [0e1.1 (e)/BBi(pr).S.8h12.2 (l)3p6.3
